lookup table for scores

# The best sequential pathway through the substitution scores is the alignment

(B) THIS-LI-NE-  
 --ISALIGNED

"dynamic programming" algorithm.

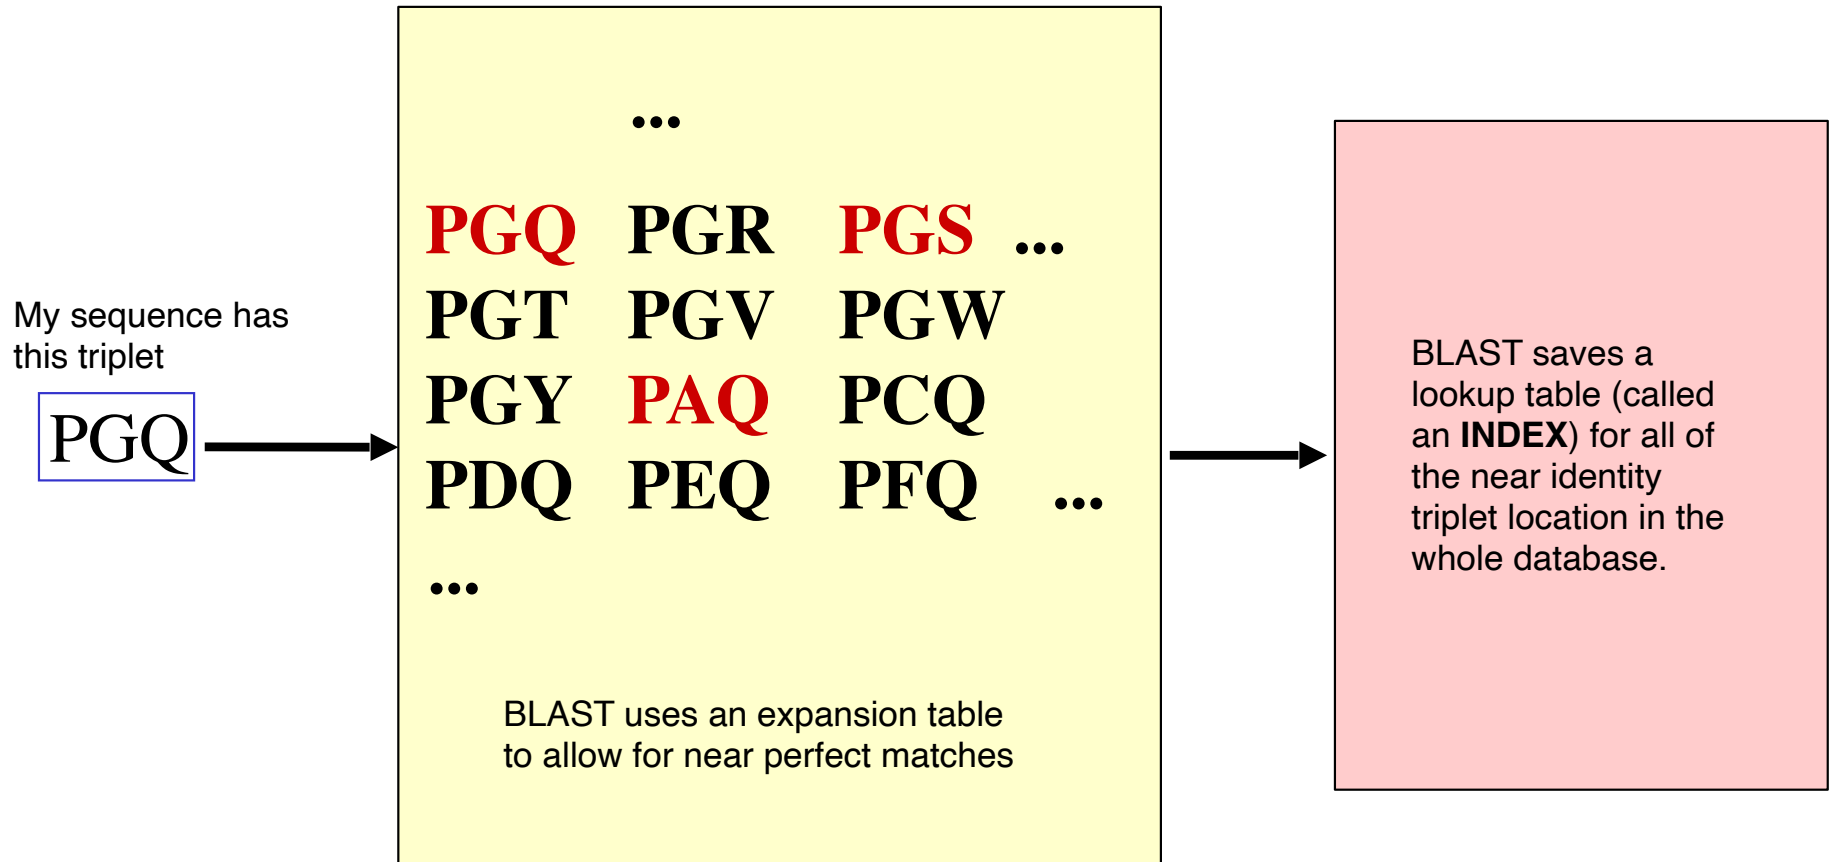

# BLAST searches millions of sequences

GenBank contains *over 162 million sequences!!*

The score for each should be the *optimal* alignment score. Even if we can do 1 per millisecond, it would take 45 hours to do one search. BLAST usually finishes in under a minute.

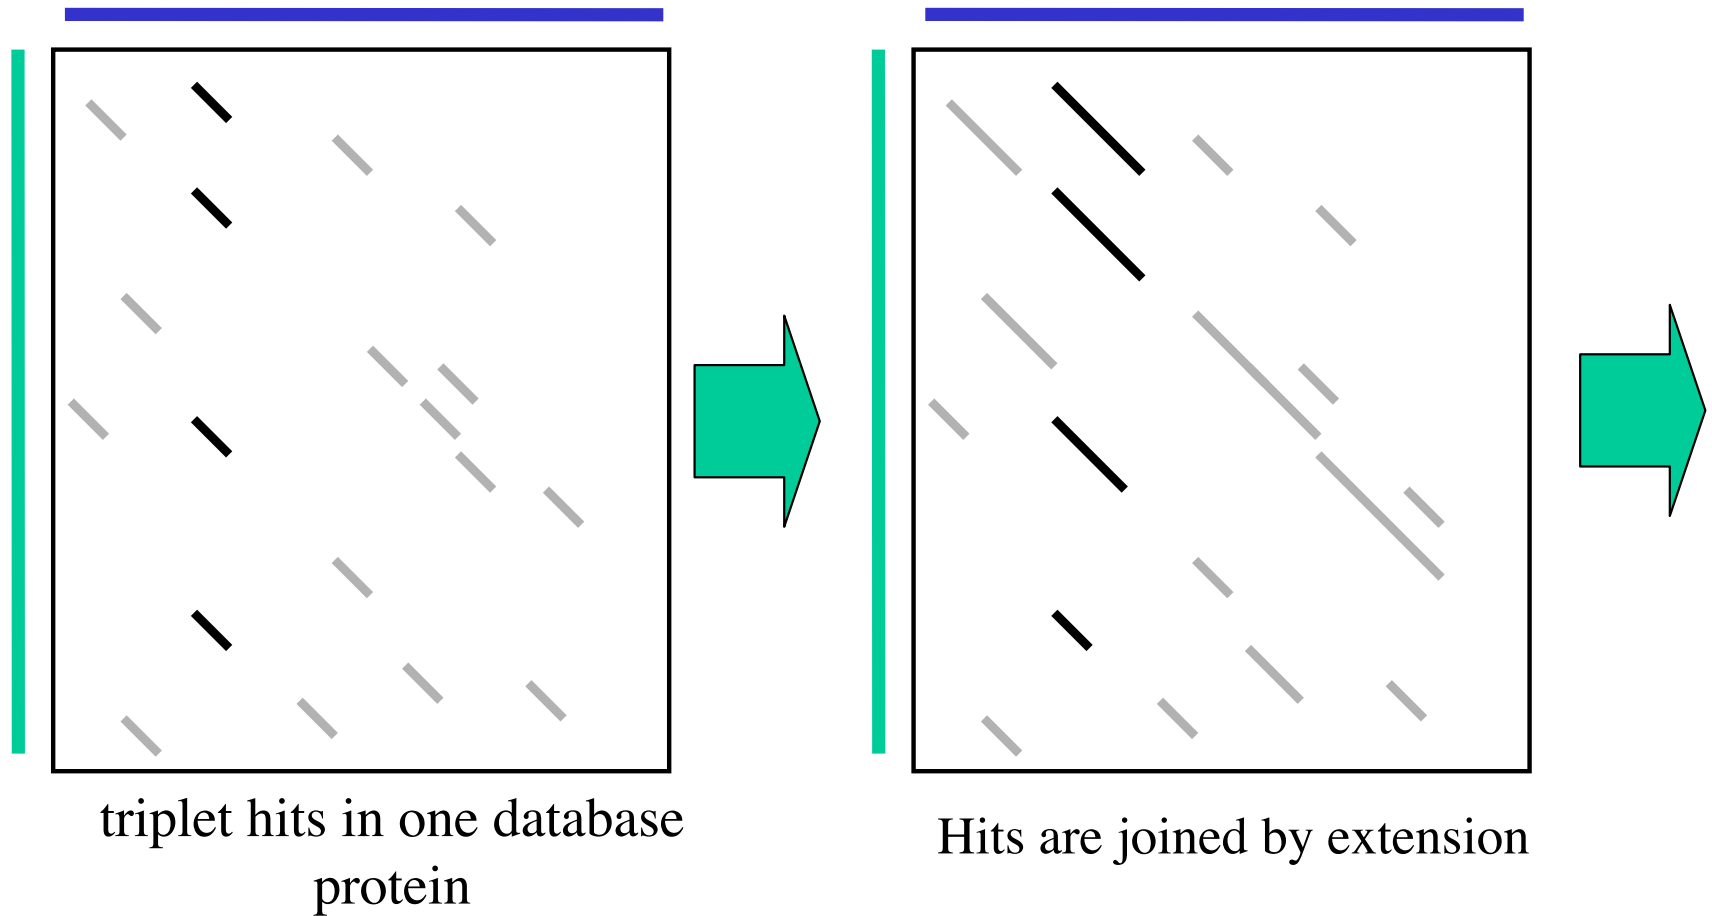

## How does BLAST do it so fast?

# BLAST precalculates all triplet hits in the database.

This is all done when BLAST is set up, before any searches are carried out.

# BLAST finds diagonal arrangements of triplet hits

# BLAST scores only the best hits (saves time)

BLAST connects the diagonals (FASTA algorithm)

This protein is given a score, and we save it for later only if the score passes a **cutoff**.

# Protein Databases available for BLAST search

Go to BLAST search page (i.e. blastp) , select a database to search and then select ? to learn a little about that database.

Non-redundant protein sequences (nr)  

**Title:** All non-redundant GenBank CDS translations+PDB+SwissProt+PIR+PRF excluding environmental samples from WGS projects  
**Molecule Type:** Protein  
**Update date:** 2017/09/20  
**Number of sequences:** 131807364

Reference proteins (refseq\_protein)  

**Title:** NCBI Protein Reference Sequences  
**Molecule Type:** Protein  
**Update date:** 2017/09/20  
**Number of sequences:** 92512280

Model Organisms (landmark)  

**Title:** Landmark database for SmartBLAST  
**Description:** The landmark database includes proteomes from 27 genomes spanning a wide taxonomic range. For more information on this database, see [http://blast.ncbi.nlm.nih.gov/smartblast/smartBlast.cgi?CMD=Web&PAGE\\_TYPE=BlastDocs](http://blast.ncbi.nlm.nih.gov/smartblast/smartBlast.cgi?CMD=Web&PAGE_TYPE=BlastDocs)  
**Molecule Type:** Protein  
**Update date:** 2015/09/09  
**Number of sequences:** 414146

# Protein Databases available for BLAST search

On BLAST search page, select a database to search and then select ? to learn a little about that database.

The screenshot displays three database selection options, each with a dropdown menu and a help icon. The selected database is highlighted in a light blue box.

- UniProtKB/Swiss-Prot(swissprot)**
  - Title:** Non-redundant UniProtKB/SwissProt sequences.
  - Molecule Type:** Protein
  - Update date:** 2017/09/20
- Patented protein sequences(pat)**
  - Title:** Protein sequences derived from the Patent division of GenBank
  - Molecule Type:** Protein
  - Update date:** 2017/09/20
  - Number of sequences:** 2054527
- Protein Data Bank proteins(pdb)**
  - Title:** PDB protein database
  - Description:** This database consists of sequences from the Protein Data Bank (PDB), which contains information about experimentally-determined structures of proteins, nucleic acids, and complex assemblies.
  - Molecule Type:** Protein
  - Update date:** 2017/09/20
  - Number of sequences:** 93500

# Protein Databases available for BLAST search

On BLAST search page, select a database to search and then select ? to learn a little about that database.

The screenshot shows a BLAST search interface with two database options. Each option is presented in a yellow header bar with a dropdown menu and a help icon. Below each header is a light blue box containing details about the database.

**Metagenomic proteins(env\_nr)**

- Title:** Proteins from WGS metagenomic projects (env\_nr).
- Molecule Type:** Protein
- Update date:** 2017/09/20
- Number of sequences:** 7003668

**Transcriptome Shotgun Assembly proteins (tsa\_nr)**

- Title:** Transcriptome Shotgun Assembly (TSA) sequences
- Description:** The Transcriptome Shotgun Assembly proteins are produced from CDS features on mRNA sequences in the Transcriptome Shotgun Assembly sequences. See <http://www.ncbi.nlm.nih.gov/genbank/TSA.html> for details.
- Molecule Type:** Protein
- Update date:** 2013/03/31
- Number of sequences:** 2382761

# How significant is that?

Please give me  
a number for...

...how likely the  
data would not  
have been the  
result of chance,...

...as  
opposed  
to...

...a specific  
inference.

# p-value

The p-value for score  $x$  is the likelihood that a chance score is greater than  $x$ .

Thus, the p-value is the probability that the result is "by chance."

*p-value* is the significance of one (1) alignment score.  
*e-value* is the significance of the highest score out of many tries.

Throwing  $n$  random darts at a normal distribution

Searching a database of 162 million sequences for one hit is like trying 162 million times to get one good high score.

So, the number of times you will see that **high score** by chance is the p-value times 162 million.

$$\text{e-value} = \text{p-value} * 162,000,000 \text{ (GenBank search)}$$

# The Extreme Value Distribution

Histograms of Random Gaussian scores, best of N tries.

N=1,2,5,10,100,1000

EVD is the "null" model for database hits.

# e-value

*A better metric of significance.*

$$\text{E-value} = \text{p-value} \times n$$

the number of tries

the likelihood of score x by chance

the expected number of times you will see a score of x or better in n tries.

# Pop-quiz

## Biology Grad Core course: Discussion Topic

Merck Smith-Kline was the author on a study of Trioxx, an anti-inflammatory drug used to treat arthritis, for which it was known to be effective. The study followed over 500 long-time Trioxx users and an equal number of control subjects who had never used the drug. Dr. Smith-Kline was looking for correlations between the use of Trioxx and the incidence of any disease other than arthritis, in any demographic group. He noted in the study that Tunisian Americans, in the age range from 45-55, male or female, and who had been a vegetarian for more than 6 months at any time in their lives, had a "strong negative correlation" between the use of Trioxx and the incidence of restless leg syndrome (RLS), and began touting Trioxx as an effective anti-RLS drug.

The numbers were as follows:

Total Tunisian American vegetarians age 45-55 : 32

Total Tunisian American vegetarians age 45-55 Trioxx users : 16

Total Tunisian American vegetarians age 45-55 Trioxx non-users : 16

Total Tunisian American vegetarians age 45-55 who have RLS : 4

Total Tunisian American vegetarians age 45-55 who do not have RLS : 28

	Trioxx non-users	Trioxx users
RLS	4	0
no RLS	12	16

Dr. Smith-Kline correctly calculated the correlation between Trioxx and RLS as follows:

Corr =, where  $u_i = 1$  if subject  $i$  is a user, and 0 otherwise,  $r_i$  is 1 if the subject has RLS and 0 otherwise.

$$\frac{\sum (u_i - \langle u \rangle)(r_i - \langle r \rangle)}{\sqrt{\sum (u_i - \langle u \rangle)^2 \sum (r_i - \langle r \rangle)^2}}$$

The sums were carried out over all 32 subjects in the subset, and the resulting correlation was -0.378. This confidence level was cited as 99%, since the p-value for this correlation was 0.01, The sample size of 32 and the uneven distribution of subjects with RLS were taken into account.

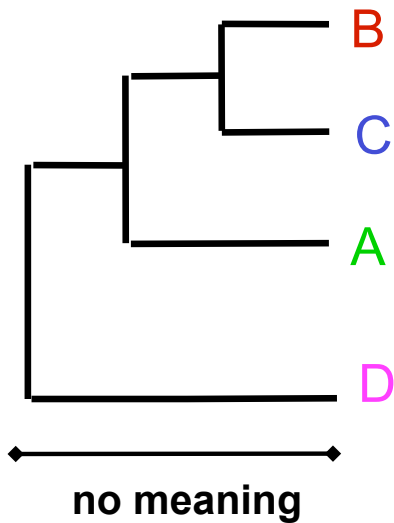

The data itself was collected correctly and the calculations were correct, both for the correlation and its confidence. Yet Merck Smith-Kline did something dishonest in this study. What was it and what specific question would you ask him to reveal his dishonesty?

# Life is not strictly a tree -- horizontal gene transfer

## Discrete Steps Needed for Stability of Gene Transfer

Stably incorporating horizontally transferred genes into a recipient genome involves five distinct steps (Fig. 1). **1.** First, a particular segment of DNA or RNA is prepared for transfer from the donor strain through one of several processes, including excision and circularization of conjugative transposons, initiation of conjugal plasmid transfer by synthesis of a mating pair-formation protein complex, or packaging of nucleic acids into phage virions. **2.** Next, the segment is transferred either by conjugation, which requires contact between the donor and recipient cells, or by transformation and transduction without direct contact. **3.** During the third step, genetic material enters the recipient cell, where cell exclusion may abort the transfer. **4.** Otherwise, during the fourth step, the incoming gene is integrated into the recipient genome by legitimate or sitespecific recombination or by plasmid circularization and complementary strand

synthesis. Barriers to transfer during this step come from restriction modification systems, failure to integrate and replicate within the new host genome, and incompatibility with resident plasmids. **5.** In the final step, transferred genes are replicated as part of the recipient genome and transmitted to daughter cells in stable fashion over successive generations. Researchers from different disciplines tend to focus on specific stages within this five-step sequence. Thus, evolutionary biologists who examine microbial genomes for evidence of past transfers tend to look at HGTs from the perspective of step five. Molecular biologists are more likely to examine the details of the transfer events, while microbial ecologists look more broadly when they describe the magnitude and diversity of the mobile gene pool, sometimes called the mobilome.

BF Smets, T Barkay (2005) "Horizontal gene transfer: perspectives at a crossroads of scientific disciplines" Nature Reviews Microbiology.

# Use orthologs to make trees

- To make the right inferences about evolution, make sure your phylogenetic tree is composed of orthologs

## How do you know it's an ortholog?

1. It has the same function in both species.
2. It has about the same number of differences across species as other orthologs.
3. Often you can't know.
